

Screenshots of the outputs of different data size:

Screenshot of the graph - Data(x-axis) vs Throughput(y-axis)

Here, we can see a positive linear relationship between throughput and data, expressed by the equation $y = 0.444102x + 12.58042$, which says that throughput increases proportionally as the size of data increases. $R^2 = 1$ means that the relationship is completely linear.
